Suppose We Have 2 Equal Features

- Input features: $x_1, x_2 \in \mathbf{R}$.
- Outcome: $y \in \mathbf{R}$.
- Linear prediction functions $f(x) = w_1 x_1 + w_2 x_2$
- Suppose $x_1 = x_2$.
- Then all functions with $w_1 + w_2 = k$ are the same.
 - give same predictions and have same empirical risk

What function will we select if we do ERM with ℓ_1 or ℓ_2 constraint?

Equal Features, ℓ_2 Constraint

- Suppose the line $w_1 + w_2 = 2\sqrt{2} + 3.5$ corresponds to the empirical risk minimizers.
- Empirical risk decreases as we move away from these parameter settings
- Intersection of $w_1 + w_2 = 2\sqrt{2}$ and the norm ball $\|w\|_2 \leq 2$ is ridge solution.
- Note that $w_1 = w_2$ at the solution

Equal Features, ℓ_1 Constraint

- Suppose the line $w_1 + w_2 = 5.5$ corresponds to the empirical risk minimizers.
- Intersection of $w_1 + w_2 = 2$ and the norm ball $\|w\|_1 \leq 2$ is lasso solution.
- Note that the solution set is $\{(w_1, w_2) : w_1 + w_2 = 2, w_1, w_2 \geq 0\}$.

Linearly Related Features

- Same setup, now suppose $x_1 = 2x_2$.
 - Then all functions with $w_1 + 2w_2 = k$ are the same.
 - give same predictions and have same empirical risk
- What function will we select if we do ERM with ℓ_1 or ℓ_2 constraint?

Linearly Related Features, ℓ_2 Constraint

- Intersection of $w_1 + 2w_2 = 10\sqrt{5}$ and the norm ball $\|w\|_2 \leq 2$ is ridge solution.
- At solution, $w_2 = 2w_1$.

Linearly Related Features, ℓ_1 Constraint

- Intersection of $w_1 + 2w_2 = 4$ and the norm ball $\|w\|_1 \leq 2$ is lasso solution.
- Solution is now a corner of the ℓ_1 ball, corresponding to a sparse solution.

Linearly Dependent Features: Take Away

- For identical features
 - ℓ_1 regularization spreads weight arbitrarily (all weights same sign)
 - ℓ_2 regularization spreads weight evenly
- Linearly related features
 - ℓ_1 regularization chooses variable with larger scale, 0 weight to others
 - ℓ_2 prefers variables with larger scale – spreads weight inversely proportional to scale

Empirical Risk for Square Loss and Linear Predictors

- Recall our discussion of linear predictors $f(x) = w^T x$ and square loss.
- Sets of w giving same empirical risk (i.e. level sets) formed ellipsoids around the ERM.

- With x_1 and x_2 linearly related, we get a degenerate ellipse.
- That's why level sets were lines (actually pairs of lines, one on each side of ERM).

KPM Fig. 13.3

Correlated Features – Same Scale

- Suppose x_1 and x_2 are highly correlated and the same scale.
- This is quite typical in real data, after normalizing data.
- Nothing degenerate here, so level sets are ellipsoids.
- But, the higher the correlation, the closer to degenerate we get.
- That is, ellipsoids keep stretching out, getting closer to two parallel lines.

Correlated Features, ℓ_1 Regularization

- Intersection could be anywhere on the top right edge.
- Minor perturbations can drastically change intersection point – very unstable solution.
- Makes division of weight among highly correlated features (of same scale) seem arbitrary.
 - If $x_1 \approx 2x_2$, ellipse changes orientation and we probably hit a corner.

Example with highly correlated features

- Model in words:
 - y is a linear combination of z_1 and z_2
 - But we don't observe z_1 and z_2 directly.
 - We get 3 noisy observations of z_1 .
 - We get 3 noisy observations of z_2 .
- We want to predict y from our noisy observations.

Example from Section 4.2 in Hastie et al's *Statistical Learning with Sparsity*.

Example with highly correlated features

- Suppose (x, y) generated as follows:

$$\begin{aligned} z_1, z_2 &\sim \mathcal{N}(0, 1) \text{ (independent)} \\ \varepsilon_0, \varepsilon_1, \dots, \varepsilon_6 &\sim \mathcal{N}(0, 1) \text{ (independent)} \\ y &= 3z_1 - 1.5z_2 + 2\varepsilon_0 \\ x_j &= \begin{cases} z_1 + \varepsilon_j/5 & \text{for } j = 1, 2, 3 \\ z_2 + \varepsilon_j/5 & \text{for } j = 4, 5, 6 \end{cases} \end{aligned}$$

- Generated a sample of (x, y) pairs of size 100.
- Correlations within the groups of x 's were around 0.97.

Example from Section 4.2 in Hastie et al's *Statistical Learning with Sparsity*.

Example with highly correlated features

- Lasso regularization paths:

- Lines with the same color correspond to features with essentially the same information
- Distribution of weight among them seems almost arbitrary

Hedge Bets When Variables Highly Correlated

- When variables are highly correlated (and same scale, after normalization),
 - we want to give them roughly the same weight.
- Why?
 - Let their error cancel out
- How can we get the weight spread more evenly?

Elastic Net

- The **elastic net** combines lasso and ridge penalties:

$$\hat{w} = \arg \min_{w \in \mathbf{R}^d} \frac{1}{n} \sum_{i=1}^n \{w^T x_i - y_i\}^2 + \lambda_1 \|w\|_1 + \lambda_2 \|w\|_2^2$$

- We expect correlated random variables to have similar coefficients.

Highly Correlated Features, Elastic Net Constraint

- Elastic net solution is closer to $w_2 = w_1$ line, despite high correlation.

Elastic Net - “Sparse Regions”

- Suppose design matrix X is orthogonal, so $X^T X = I$, and contours are circles (and features uncorrelated)
- Then OLS solution in green or red regions implies elastic-net constrained solution will be at corner

Fig from Mairal et al.'s *Sparse Modeling for Image and Vision Processing* Fig 1.9

Elastic Net – A Theorem for Correlated Variables

Theorem

^aLet $\rho_{ij} = \widehat{\text{corr}}(x_i, x_j)$. Suppose \hat{w}_i and \hat{w}_j are selected by elastic net. If $\hat{w}_i \hat{w}_j > 0$, then

$$|\hat{w}_i - \hat{w}_j| \leq \frac{\|y\| \sqrt{2}}{\lambda_2} \sqrt{1 - \rho_{ij}}.$$

Elastic Net Results on Model

- Lasso on left; Elastic net on right.
- Ratio of ℓ_2 to ℓ_1 regularization roughly 2 : 1.

Elastic Net vs Lasso Norm Ball

The $(\ell_q)^q$ Norm Constraint

- Generalize to ℓ_q norm: $(\|w\|_q)^q = |w_1|^q + |w_2|^q$.
- $\mathcal{F} = \{f(x) = w_1 x_1 + w_2 x_2\}$.
- Contours of $\|w\|_q^q = |w_1|^q + |w_2|^q$:

$\ell_{1.2}$ vs Elastic Net

FIGURE 3.13. *Contours of constant value of $\sum_j |\beta_j|^q$ for $q = 1.2$ (left plot), and the elastic-net penalty $\sum_j (\alpha \beta_j^2 + (1 - \alpha) |\beta_j|)$ for $\alpha = 0.2$ (right plot). Although visually very similar, the elastic-net has sharp (non-differentiable) corners, while the $q = 1.2$ penalty does not.*
