Regression Loss Functions

Loss Functions for Regression

- In general, loss function may take the form

$$(\hat{y}, y) \mapsto \ell(\hat{y}, y) \in \mathbf{R}$$

- Regression losses usually only depend on the **residual** $r = y - \hat{y}$.
- Loss $\ell(\hat{y}, y)$ is called **distance-based** if it
 - 1 only depends on the residual:

$$\ell(\hat{y}, y) = \psi(y - \hat{y}) \quad \text{for some } \psi: \mathbf{R} \rightarrow \mathbf{R}$$

- 2 loss is zero when residual is 0:

$$\psi(0) = 0$$

Distance-Based Losses are Translation Invariant

- Distance-based losses are translation-invariant. That is,

$$\ell(\hat{y} + a, y + a) = \ell(\hat{y}, y).$$

- When might you not want to use a translation-invariant loss?
- e.g. Sometimes relative error is a more natural loss (but not translation-invariant)
- Often you can transform response y so it's translation-invariant (e.g. log transform)
 - See homework or concept check questions.

Some Losses for Regression

- **Square** or ℓ_2 Loss: $\ell(r) = r^2$
- **Absolute** or **Laplace** or ℓ_1 Loss: $\ell(r) = |r|$

y	\hat{y}	$ r = y - \hat{y} $	$r^2 = (y - \hat{y})^2$
1	0	1	1
5	0	5	25
10	0	10	100
50	0	50	2500

- Outliers typically have large residuals.
- Square loss much more affected by outliers than absolute loss.

Loss Function Robustness

- **Robustness** refers to how affected a learning algorithm is by outliers.

KPM Figure 7.6

Some Losses for Regression

- **Square** or ℓ_2 Loss: $\ell(r) = r^2$ (*not robust*)
- **Absolute** or **Laplace** Loss: $\ell(r) = |r|$ (*not differentiable*)
 - gives **median regression**
- **Huber** Loss: Quadratic for $|r| \leq \delta$ and linear for $|r| > \delta$ (*robust and differentiable*)

- x-axis is the residual $y - \hat{y}$.

Classification Loss Functions

The Classification Problem

- Outcome space $\mathcal{Y} = \{-1, 1\}$
- Action space $\mathcal{A} = \{-1, 1\}$
- **0-1 loss** for $f : \mathcal{X} \rightarrow \{-1, 1\}$:

$$\ell(f(x), y) = 1(f(x) \neq y)$$

- But let's allow **real-valued predictions** $f : \mathcal{X} \rightarrow \mathbf{R}$:

$$f > 0 \implies \text{Predict } 1$$

$$f < 0 \implies \text{Predict } -1$$

The Score Function

- Action space $\mathcal{A} = \mathbf{R}$ Output space $\mathcal{Y} = \{-1, 1\}$
- **Real-valued prediction function** $f : \mathcal{X} \rightarrow \mathbf{R}$

Definition

The value $f(x)$ is called the **score** for the input x .

- In this context, f may be called a **score function**.
- Intuitively, magnitude of the score represents the **confidence of our prediction**.

The Margin

Definition

The **margin** (or **functional margin**) on an example (x, y) is $yf(x)$.

- The margin is a measure of how **correct** we are.
- We want to **maximize the margin**.
- Most classification losses depend only on the margin.

(In Lab, we will discuss a related concept called the **geometric margin**.)

The Classification Problem: Real-Valued Predictions

- Empirical risk for 0 – 1 loss:

$$\hat{R}_n(f) = \frac{1}{n} \sum_{i=1}^n 1(y_i f(x_i) \leq 0)$$

Minimizing empirical 0 – 1 risk not computationally feasible

$\hat{R}_n(f)$ is non-convex, not differentiable (in fact, discontinuous!).

Optimization is **NP-Hard**.

Classification Losses

Zero-One loss: $\ell_{0-1} = 1(m \leq 0)$

- x-axis is **margin**: $m > 0 \iff$ correct classification

Classification Losses

SVM/Hinge loss: $\ell_{\text{Hinge}} = \max\{1 - m, 0\} = (1 - m)_+$

Hinge is a **convex, upper bound** on 0–1 loss. Not differentiable at $m = 1$.
We have a “margin error” when $m < 1$.

(Soft Margin) Linear Support Vector Machine

- Hypothesis space $\mathcal{F} = \{f(x) = w^T x \mid w \in \mathbf{R}^d\}$.
- Loss $\ell(m) = (1 - m)_+$
- ℓ_2 regularization

$$\min_{w \in \mathbf{R}^d} \sum_{i=1}^n (1 - y_i f_w(x_i))_+ + \lambda \|w\|_2^2$$

Classification Losses

Logistic/Log loss: $\ell_{\text{Logistic}} = \log(1 + e^{-m})$

Logistic loss is differentiable. Logistic loss always wants more margin (loss never 0).

What About Square Loss for Classification?

- Action space $\mathcal{A} = \mathbf{R}$ Output space $\mathcal{Y} = \{-1, 1\}$
- Loss $\ell(f(x), y) = (f(x) - y)^2$.
- Turns out, can write this in terms of margin $m = f(x)y$:

$$\ell(f(x), y) = (f(x) - y)^2 = (1 - m)^2$$

- Prove using fact that $y^2 = 1$, since $y \in \{-1, 1\}$.

What About Square Loss for Classification?

Heavily penalizes outliers.

Seems to have higher sample complexity (i.e. needs more data) than hinge & logistic¹.
